## **Summary**

The present study was performed to provide a detailed anatomic description and computed tomographic (CT) measurements of the structures of the head in 30 clinically normal Saanen goats weighing 50 to 80 kg. Pre- and post-contrast transverse images of the head were obtained with a 40-slice CT scanner. Subsequently, 13 animals were euthanized and frozen. The heads were then sliced into 10 mm transverse sections of which the caudal aspect was photographed. Corresponding CT and anatomic images were compared and labeled. The extensions of the frontal, maxillary, lacrimal and palatine sinuses and the width and location of the openings of the maxillary sinuses and the frontal sinuses were described. The pituitary density and dimensions, pituitary height/brain area ratio as well as the sum of the areas of the lateral ventricles/brain area ratio were measured. In two goats, dynamic CT of the hypophysis was performed. Most features of the head that were identified on anatomic sections could be identified on the corresponding CT scans. In conclusion, the CT images and measurements obtained in this study can be used as a reference for the evaluation of the head in goats with diseases in this region.

## **Introduction**

Goats are gaining acceptance as a model for biomedical research, for surgical training and for teaching. They are used in medical, orthopedic, chemotherapeutic, and physiologic research (Baisden et al., 1999; Fulton KL, 1994; Leung et al., 2001; Liu et al., 2008; ten Hallers et al., 2007; ten Hallers et al., 2004). Additionally, the Saanen goat represents a popular dairy breed in Switzerland and is commonly presented in the hospital population. The role of goats has significantly changed in our society during the last years being increasingly considered companion animals.

Computed tomography (CT) is a reliable, noninvasive technique for the evaluation of lesions in the head region (Allen et al., 1987; Barrington, 1996; Bergman et al., 2000; Ducote et al., 1999; Fike et al., 1981; Fike, 1986; Frazho et al., 2008; Gerros et al., 1998; Gonzalo-Orden et al., 1999; Nykamp et al., 2001; Plummer S, 1992; Smallwood et al., 2002; Tidwell A, 1994; Tietje et al., 1996; Vink-Nooteboom et al., 1998; Wolf M, 1995; Woods P, 1993). During recent years, the technique has become available to veterinarians and some private veterinary practices. In the veterinary literature, a number of publications describe the normal CT anatomy of the head of horses (Morrow et al., 2000; Smallwood et al., 2002), dogs and cats. The CT anatomy of the canine brain (De Rycke et al., 2005), pituitary gland (van der Vlucht-Meijer et al., 2004; Van der Vlucht-Meijer et al., 2007), nasal cavity and paranasal sinuses (De Rycke et al., 2003), middle and inner ear (Russo et al., 2002) and temporomandibular joint (Schwarz et al., 2002) has been published. The anatomy of the feline nasal cavity and paranasal sinuses (Losonsky, 1997), nasolacrimal drainage system (Noller et al., 2006) and pituitary gland (Tyson et al., 2005) has also been reported by means of CT. A detailed description of the communications of the normal equine nasal and paranasal cavities (Probst et al., 2005) as well as CT measurements of the normal equine pituitary gland (McKlveen et al., 2003) are available. Several pathologic conditions of the brain, ear, nasal and oral cavities, paranasal sinuses and temporomandibular joint have been investigated and diagnosed by

means of CT in goats, horses, dogs, cats and sheep (Allen et al., 1987; Bergman et al., 2000; Ducote et al., 1999; Fike et al., 1981; Fike, 1986; Frazho et al., 2008; Gerros et al., 1998; Gonzalo-Orden et al., 1999; Marshall et al., 1995; Nykamp et al., 2001; Plummer S, 1992; Tidwell A, 1994; Tietje et al., 1996; Vink-Nooteboom et al., 1998; Wolf M, 1995; Woods P, 1993). With regard to the caprine head, CT has proven to be useful in the diagnosis of paranasal sinusitis (Barrington, 1996), primary brain neoplasia (Marshall et al., 1995) and a cerebral abscess (Gerros et al., 1998). To accurately interpret CT scans, a thorough knowledge of the anatomic features of clinically normal animals is a prerequisite. So far, there are no reports in the literature about the normal CT anatomy of the head of goats.

Therefore, the purpose of this study was to provide a detailed anatomic description of the structures of the head in clinically normal goats by means of CT for use by radiologists, clinicians, researchers and veterinary students.

## **Materials and methods**

For the present study, 30 dairy goats of the Saanen breed were included. Mean age of the goats was 4.3 years (SD, 1.2 years). Mean body weight was 62.3 kg (SD, 7.9 kg). All goats underwent a clinical examination, complete blood analysis, urinalysis, rumen fluid analysis and parasitological fecal examination. None of the animals had a history of neurological, upper airway or upper gastrointestinal tract disorders. Serological testing for caprine arthritis and encephalitis had to be negative in all animals. The study was approved by the Animal Ethics Council of the Canton of Zurich.

Each goat was anesthetized and positioned in sternal recumbency. Transverse contiguous slices were obtained from the head. Technical settings were 120 KV, 350 mA, 1 s tube rotation, and slice collimation of 0.6 cm. The CT study was performed with a multi-row unit (Somatom Sensation Open, Siemens AG Medical Solutions, Switzerland). The data was reconstructed to image series with 0.75 mm slice thickness using a medium-frequency image reconstruction algorithm (soft tissue) and a high-frequency image reconstruction algorithm (bone). Using the same settings, a post-contrast examination was performed in 11 animals. The scan was started 120 seconds after injection of an ionic iodinated contrast medium at a dosage of 700mg/kg using an automatic injector at a rate of 4ml/s into the jugular vein. For the brain and skull, a soft tissue window (window width, 150 Hounsfield units; window level, 50 Hounsfield units) and a bone window (window width, 1500 Hounsfield units; window level, 300 Hounsfield units) were used. For the nasal cavity, the bone window was applied. For the pituitary gland, a different soft tissue window was used according to the literature (window width, 250 Hounsfield units; window level, 80 Hounsfield units) (Auriemma, Voorhout et al. 2007). Thirteen goats were euthanized immediately after the CT examination and subsequently transferred into a freezer for at least 3 days. The rest of the animals were slaughtered and no anatomical or pathological information was obtained. A band saw was used to slice the frozen heads into contiguous 10 mm transverse (10 goats), and sagittal (3

goat) sections. Each anatomic frozen slice was cleaned with water, and the caudal aspect photographed with a digital camera. For each photograph, a corresponding CT image was selected. Matched pairs of images of the head were obtained at 16 transverse and 1 mid-sagittal levels. The anatomic structures, identified on the photographs by use of anatomic reference texts, were subsequently located on the corresponding CT images (with and without contrast material).

On the transverse CT images, the extension of the frontal, maxillary, lacrimal and palatine sinuses was evaluated. The premolars and molars were used as landmarks to estimate the rostral and caudal extensions of the palatine sinus and caudal extension of the lacrimal sinus. The infraorbital foramen was used as the landmark to estimate the rostral extension of the maxillary sinus. The rostral contour of the orbit and the supraorbital foramen were used as landmarks to define the rostral and caudal extensions of the frontal sinus respectively. The width and location of the openings of the maxillary and frontal sinuses into the medial nasal meatus relative to the premolars and molars were evaluated.

The maximum height, width and length of the pituitary gland were measured in the post-contrast series from transverse and sagittal images. Three-dimensional volume measurements were obtained by hand tracing the outlines of the pituitary gland in sequential transverse images and by use of the workstation's software (OsiriX Open Source™ Version 3.2.1, OsiriX Foundation, Switzerland) for volume determination. On the same image where the pituitary height was measured, the brain area and the areas of the right and left lateral ventricle were obtained by hand tracing the outlines of the brain and the lateral ventricles. The computer automatically calculated the area. Then, the pituitary height/brain area ratio and the sum of the areas of the lateral ventricles/brain area ratio were calculated. To evaluate the pre- and post-contrast density of the pituitary gland, a round ROI was displayed on the gland including as much gland tissue as possible without including surrounding structures.

In two goats a dynamic CT of the hypophysis was performed. A series of 10 dynamic helical scans was performed at the level of the pituitary gland from rostral to caudal; the first scan was obtained with the onset of the contrast medium injection. The interscan interval was 10 seconds. Density measurements (HU) and time-attenuation curves of the maxillary artery, rete mirabile, the rostradorsal and the dorsocaudal aspect of the pituitary gland were acquired.

The height and width of the pituitary gland were also measured from the anatomical specimen using the slice containing the largest cross section of the pituitary gland. The rest of the animals were slaughtered and no anatomical or pathological information was obtained.

Agreement between the anatomical and CT measurements of the pituitary gland was analyzed with the Bland and Altman plot method (MedCalc Software, Version 11.2.1.0, Belgium).

## Results

All the anatomical specimens and the CT examinations were reviewed but only selected images are presented. Sixteen transverse CT planes of the head were obtained and matched with their corresponding anatomic sections (Figures 1-16). Of the sagittal sections, only the midsagittal plane is presented (Figure 17). In general, structures identified on the anatomic sections were also identified on the corresponding CT images without and with contrast material.

On evaluation of the post-contrast images, the salivary glands, lymph nodes, blood vessels and intracranial structures such as the hypophysis and the falx cerebri were much more distinct compared to the pre-contrast CT images. For example, although the pituitary fossa was easily identified in the pre-contrast study, the contours of the pituitary gland could hardly be depicted due to the minimal difference in density between the gland and the surrounding cavernous sinus (Figure 11). On the post-contrast images, the pituitary gland was identified in all animals due to a different degree of enhancement of the hypophysis compared to the surrounding cavernous sinus.

The extension of the sinuses was bilaterally symmetrical, therefore only one measurement of the rostral extension and one measurement of caudal extension of each sinus are provided. The palatine sinus extended 0.5 cm rostral to the maxillary second premolar (P2) in 4 animals, to the level of P2 in 18 animals, to a level between P2 and third premolar (P3) in 6 animals and to the level of P3 in 2 animals (Figure 18). The palatine sinus extended caudally to the level of the third maxillary molar (M3) in 24 animals and to the level of a line between second maxillary premolar (M2) and M3 in 6 animals (Figure 18). The lacrimal sinus extended to the level of M3 in 13 animals, 0.5 cm caudally to M3 in 6 animals, 1 cm caudally to M3 in 8 animals, 1.5 cm caudally to M3 in 2 animals and 2 cm caudally to M3 in 1 animal (Figure 1). The opening of the maxillary sinus into the nasal cavity was located at the level of fourth premolar (P4) in 15 animals and at first maxillary molar (M1) in 15 animals. The mean

width of the opening between the maxillary sinus and the nasal cavity (Figure 19) was 0.15 cm (SD, 0.16 cm). The lateral compartment of the frontal sinus always extended a few millimeters rostral compared to the medial compartment. Considering that this minimal difference in extension is clinically irrelevant, only the measurement of the lateral compartment was presented. The rostral contour of the orbit was used as the landmark to measure the rostral extension of the frontal sinuses. In 5 animals the frontal sinus extended 1 cm, in 6 animals 2 cm, in 11 animals 3 cm, in 6 animals 4 cm and in 2 animal 5 cm to the rostral aspect of the orbit. The frontal sinus extended 5 cm caudally to the supraorbital foramen in 1 animal, 6 cm in 12 animals, 7 cm in 10 animals and 8 cm in 7 animals (Figure 18). The opening of the frontal sinus into the nasal cavity was located at the level of M2 in 16 animals, at the level of a line between M2 and M3 in 7 animals and to the level of M3 in 7 animals. The mean width of the openings of the lateral and medial compartments of the frontal sinus into the nasal cavity was 0.17 cm (SD, 0.6 cm).

Mean CT measurements for the pituitary gland were: height 1.0 cm (SD, 0.16 cm); width 1.0 cm (SD, 0.1 cm) and length 1.6 cm (SD, 0.22 cm). Mean pituitary gland volume was  $0.8 \text{ cm}^3$  (SD,  $0.2 \text{ cm}^3$ ). Mean brain area was  $22.0 \text{ cm}^2$  (SD,  $1.57 \text{ cm}^2$ ). Mean pituitary height/ brain area ratio was  $0.45 \text{ mm}^{-1}$  (SD,  $0.06 \text{ mm}^{-1}$ ). Mean area of the right and left lateral ventricle was  $0.36 \text{ cm}^2$  (SD,  $0.1 \text{ cm}^2$ ) and  $0.38 \text{ cm}^2$  (SD,  $0.11 \text{ cm}^2$ ), respectively. The sum of the areas of the lateral ventricles/brain area ratio was 0.03 (SD, 0.01). In 2 goats the lateral ventricles could not be detected. Mean pre- and post-contrast pituitary density was 52 HU (SD, 5 HU) and 108 HU (SD, 12 HU), respectively.

Both dynamic CT studies of the pituitary gland presented the same pattern with an early enhancement of the maxillary arteries, the rete mirabile, the intracranial part of the internal carotid arteries and caudodorsal aspect of the pituitary gland with a time to peak enhancement 30 seconds after the start of the contrast medium injection (Figure 21). This was followed by a focal area of strong enhancement located in the rostradorsal aspect of the

pituitary gland with a time to peak enhancement of 40 seconds (Figure 21). On the last images of the dynamic study obtained 90 seconds after the contrast administration, the gland presented a homogeneous enhancement. In the anatomic specimen, all pituitary glands appeared normal macroscopically. Measurements of the pituitary height and width were obtained from 11 animals, in 2 goats the pituitary gland was sliced only in its most rostral aspect and therefore, they were excluded. Mean anatomic height and width of the pituitary gland were 0.9 cm (SD, 0.2 cm) and 1.0 cm (SD, 0.1 cm), respectively. Comparing CT measurements with anatomical measurements of the pituitary gland, the 95% limits of agreement were -0.42 to 0.26 for width and -0.08 to 0.29 for height.

## Discussion

The present study was performed to locate and measure anatomic features of the head of clinically normal goats of the Saanen breed by use of multi-slice CT.

The studies were performed with a 40-row CT unit with a slice collimation of 0.6 cm and the images were then reconstructed into 0.75 mm slices. As already reported, large volume coverage and improved resolution can be achieved with multi-row CT scanners (Esteve-Ratsch, Kneissl et al. 2001). As proven in this study, excellent reconstructed images can be generated from thin collimated slices obtained in the transverse plane. CT is an excellent modality to evaluate structures with a high natural contrast such as the nasal cavity and paranasal sinus system (Losonsky 1997; Morrow, Park et al. 2000; Smallwood, Wood et al. 2002; De Rycke, Saunders et al. 2003). The anatomic complexity of the facial bones and nasal turbinates (endoturbinates I and II, maxilloturbinate) can be overcome by use of cross-sectional diagnostic techniques including CT and Magnetic Resonance Imaging (MRI) (De Rycke, Saunders et al. 2003). Excellent images of the bone and soft tissue components of the paranasal sinuses and nasal cavity were obtained in the present study. The openings of the paranasal sinuses into the nasal cavity could be identified in all goats.

Numerous structures of the brain identified on anatomic sections were also identified on the CT images. The distinctions among internal brain structures were frequently difficult because of the minor density differences on CT images; therefore landmarks such as radiolucent CSF and bony structures were used for orientation. The use of contrast medium enhanced the visualization of certain intra-cranial structures, such as the pituitary gland, choroid plexus, cavernous sinus, falx cerebri and arterial cerebral circle. This was particularly important for the identification of the pituitary gland. Other structures that exhibited post-contrast enhancement were the salivary glands and the lymph nodes. The post contrast enhancement clearly helped to delineate these structures from the surrounding subcutaneous tissues and muscles. Although MRI is known to be superior to CT for the evaluation of soft

tissue structures, (LeCouteur, 1999) CT represents a valuable modality for the assessment of soft tissues such as the brain if MRI is not available.

The quantification of the enhancement of the pituitary gland in the post-contrast examinations has a questionable value considering that many parameters such as injection rate, contrast dose, injection time and body weight can influence this measurement (Awai, Hiraishi et al. 2004).

CT measurements of the width of the pituitary gland agreed well with the anatomical measurements; however, with CT, pituitary height was always measured higher than on the anatomical specimen. We speculate that the impossibility to always slice the pituitary gland at the same level and at its maximum size may have been a source of error in this measurement. Another interesting finding was the pituitary height/brain area ratio of 0.45 mm in the goat, which is higher than the reported mean value for the dog (Voorhout, Stolp et al. 1988). A relatively large pituitary gland compared to other domestic species has been reported in the sheep (Venzke, 1975). Based on our findings, this relative large pituitary gland size may also be present in goats.

Similar to other species, the adenohypophysis and neurohypophysis are separately vascularized in goats (Dyce 2002). Due to the presence of the rete mirabile, there is no single artery corresponding to the caudal hypophyseal artery in man or in the dog. Instead, one major and multiple small arteries originating from the rete replace them (Daniel and Prichard 1958). Through these vessels, the neurohypophysis has a direct arterial blood supply. The adenohypophysis is supplied indirectly, receiving its blood from veins (Dyce 2002). The anterior hypophyseal arteries originate from the internal carotid artery shortly after the posterior communicating arteries have been given off forming a ring around the rostral part of the pituitary stalk. From this ring, numerous branches run along the stalk to supply a first capillary bed within it. Hypophyseal portal vessels drain the blood from this capillary network; then, they run ventrally and caudally along the stalk and carry the blood to a second

capillary bed in the adenohypophysis. These portal vessels are the sole source from which almost the whole of the anterior lobe receives its blood supply. The capillary network of the adenohypophysis subsequently drains into the cavernous sinus (Daniel and Prichard 1958). In both dynamic studies, two focal enhancing areas with different time to peak enhancement were observed in the pituitary gland. The first area of enhancement most likely represented the neurohypophysis due to its location in the caudodorsal aspect of the gland and its early enhancement. The second focal area of enhancement occurred 10 seconds after the peak enhancement of the neurohypophysis and was located in the rostradorsal part of the pituitary gland. Considering the time of enhancement and its location, this second focal area of enhancement most likely represented portal veins extending through the stalk into the adenohypophysis. In people undergoing dynamic CT, enhancement of the internal carotid artery was observed followed by enhancement of the central part of the secondary capillary bed of the adenohypophysis, which has been called the pituitary tuft (Bonneville, Cattin et al. 1983). Similar findings characterized by a strong and early enhancement of the central part of the pituitary gland was observed in dogs (Love, Fisher et al. 2000; van der Vlugt-Meijer, Meij et al. 2004; Van der Vlugt-Meijer, Meij et al. 2007). Due to anatomical differences between human and canine pituitary glands, this focal area of enhancement was interpreted as the neurohypophysis and was called the pituitary flush (van der Vlugt-Meijer, Meij et al. 2004). In the study reported here, the enhancement of both, the neurohypophysis and adenohypophysis could be identified independently.

An interesting finding in this study is the homogeneous size of the lateral ventricles and the similar ratio of the lateral ventricles area to brain area between animals. This contrasts with the values reported in dogs where statistically significant differences in ventricle size were identified between different breeds of dogs (Esteve-Ratsch, Kneissl et al. 2001). In two goats, the lateral ventricles could not be identified on CT; no intracranial abnormalities other than that were found either with CT or on the anatomic specimen. Small ventricles may

represent a normal variation, however, pathologic processes like bleeding, inflammation or neoplasia cannot be ruled out. Unfortunately, pathological information was not available.

Regarding the measurement of the extension of the paranasal sinuses, in order to have a clinical application, palpable structures such as the supraorbital foramen, the cranial contour of the orbit and the maxillary teeth were used. Our results regarding the caudal and cranial extensions of the frontal sinus are similar to those reported in the literature (Sisson 1975). The communications of the medial and lateral compartments of the frontal sinus with the nasal cavity (olfactory part of the middle nasal meatus) as well as the communications of the medial compartment of the maxillary sinus with the nasal cavity were very small but could be identified with CT in all animals.

In conclusion, a thorough knowledge of the anatomic features of the head in clinically normal goats is a prerequisite for accurate interpretation of CT changes with pathologic conditions. Therefore, the present CT atlas and the measurements obtained in this study can be as a reference for the evaluation of the head in goats.

## Figures

Figures 1-16: Images of the head of a clinically normal goat. On the top left CT image (topogram), the green vertical line illustrates the level of the transverse CT image. The mid left photograph represents the transverse anatomic section with the corresponding transverse pre-contrast CT image in a bone window (mid right), and pre-contrast (bottom left) and post-contrast (bottom right) CT images in a soft tissue window. Left is to the left and right is to the right in the images.

**Figure 1**

Figure 1: Images of the head of a clinically normal goat at the level of the second premolars:

(1) nasal bone; (2) maxilla; (3) palatine process of the maxilla; (4) dorsal nasal meatus; (5) dorsal nasal concha; (6) dorsal spiral lamella of the ventral nasal concha; (7) ventral spiral lamella of the ventral nasal concha; (8) common nasal meatus; (9) palatine sinus; (10) dorsal nasal vein; (11) dorsal labial vein; (12) nasomaxillary fissure; (13) ventral labial vein.

**Figure 2**

Figure 2: Images of the head of a clinically normal goat at the level of the third premolars:

(1) nasal bone; (2) maxilla; (3) dorsal nasal meatus; (4) middle nasal meatus; (5) dorsal nasal concha; (6) ventral nasal concha; (7) common nasal meatus; (8) nasal septum; (9) ventral nasal meatus; (10) palatine sinus; (11) dorsal nasal vein; (12) dorsal labial vein; (13) ventral labial vein; (14) palatine process of the maxilla; (15) infraorbital canal.

**Figure 3**

Figure 3: Images of the head of a clinically normal goat at the level of the third premolars:

(1) nasal bone; (2) maxilla; (3) dorsal nasal meatus; (4) middle nasal meatus; (5) dorsal nasal concha; (6) ventral nasal concha; (7) common nasal meatus; (8) nasal septum; (9) ventral nasal meatus; (10) palatine sinus; (11) nasolacrimal canal; (12) opening of the maxillary sinus into the middle nasal meatus; (13) ventral labial vein; (14) facial vein; (15) infraorbital canal; (16) nasomaxillary fissure; (17) maxillary sinus; (18) tongue.

**Figure 4**

Figure 4: Images of the head of a clinically normal goat at the level of the first molars:

(1) nasal bone; (2) maxilla; (3) dorsal nasal meatus; (4) palatine process of the maxilla; (5) dorsal nasal concha; (6) ventral nasal concha; (7) common nasal meatus; (8) vomer; (9) nasopharyngeal meatus; (10) palatine sinus; (11) angularis oculi vein; (12) transverse facial artery; (13) ventral labial vein; (14) facial vein; (15) infraorbital canal; (16) nasolacrimal canal; (17) maxillary sinus; (18) tongue; (19) lacrimal bone; (20) middle nasal concha; (21) second upper (maxillary) molar; (22) sublingual vein; (23) lingual artery; (24) mandible.

**Figure 5**

Figure 5: Images of the head of a clinically normal goat at the level of the second molars:

(1) frontal bone; (2) maxilla; (3) dorsal nasal meatus; (4) dorsal nasal concha; (5) middle nasal concha; (6) common nasal meatus; (7) vomer; (8) nasopharyngeal meatus; (9) palatine sinus; (10) angularis oculi vein; (11) pharyngeal fold; (12) facial vein; (13) ventral labial vein; (14) infraorbital canal; (15) nasolacrimal canal; (16) maxillary sinus; (17) lacrimal bone; (18) palatine bone; (19) nasal septum; (20) zygomatic bone; (21) frontal sinus.

**Figure 6**

Figure 6: Images of the head of a clinically normal goat at the level of the rostral third of the orbit:

(1) frontal bone; (2) maxilla; (3) dorsal nasal meatus; (4) perpendicular lamina palatine bone; (5) ethmoid conchae; (6) eyeball; (7) vomer; (8) nasopharyngeal meatus; (9) lateral frontal sinus; (10) medial frontal sinus; (11) lacrimal bulla; (12) masseter muscle; (13) medial pterygoid muscle; (14) transverse facial artery; (15) deep facial vein; (16) facial vein; (17) zygomatic bone, (18) tongue.

**Figure 7**

Figure 7: Images of the head of a clinically normal goat at the level of the middle third of the orbit:

(1) frontal bone; (2) fossa for the olfactory bulbs (fossa ethmoidalis); (3) supraorbital canal; (4) perpendicular lamina of palatine bone; (5) ethmoid conchae; (6) zygomatic process of the frontal bone; (7) eyeball; (8) pharyngeal septum; (9) nasopharyngeal meatus; (10) lateral frontal sinus; (11) medial frontal sinus; (12) zygomatic process of the zygomatic bone; (13) masseter muscle; (14) medial pterygoid muscle; (15) transverse facial artery; (16) mandible; (17) facial vein; (18) tongue.

## Figure 8

Figure 8: Images of the head of a clinically normal goat at the level of the caudal third of the orbit:

(1) frontal bone; (2) fossa for the olfactory bulbs (fossa ethmoidalis); (3) supraorbital canal; (4) perpendicular lamina palatine; (5) ethmoid concha; (6) zygomatic process of the frontal bone; (7) eyeball; (8) pharyngeal septum; (9) nasopharyngeal meatus; (10) lateral frontal sinus; (11) medial frontal sinus; (12) zygomatic process of the zygomatic bone; (13) masseter muscle; (14) medial pterygoid muscle; (15) transverse facial artery; (16) mandible; (17) facial vein; (18) tongue; (19) crista galli.

**Figure 9**

Figure 9: Images of the head of a clinically normal goat at a level immediately caudal to the second maxillary molars:

(1) frontal bone; (2) mandibular lymph node; (3) pterygoid bone; (4) presphenoid bone; (5) temporal muscle; (6) frontal lobe of cerebral hemisphere; (7) longitudinal cerebral fissure; (8) pharyngeal septum; (9) nasopharyngeal duct; (10) lateral frontal sinus; (11); external muscles of the eye; (12) zygomatic arch; (13) masseter muscle; (14) medial pterygoid muscle; (15) tongue; (16) mandible.

# Figure 10

Figure 10: Images of the head of a clinically normal goat at the level of the coronoid process of the mandible:

(1) frontal bone; (2) mandibular lymph node; (3) mandibular alveolar artery and vein; (4) presphenoid bone; (5) precomissural fornix; (6) frontal lobe of cerebral hemisphere; (7) caudate nucleus; (8) pharyngeal septum; (9) nasopharynx; (10) lateral frontal sinus; (11) transverse facial artery; (12) zygomatic arch; (13) masseter muscle; (14) medial pterygoid muscle; (15) pterygoid process of the basisphenoid; (16) mandible; (17) lateral ventricle; (18) corpus callosum; (19) optic chiasm; (20) chiasmatic sulculus; (21) coronoid process of the mandible; (22) lateral pterygoid muscle.

**Figure 11**

Figure 11: Images of the head of a clinically normal goat at the level of the temporomandibular joints:

(1) frontal bone; (2) mandibular lymph node; (3) parietal bone; (4) basisphenoid bone; (5) fornix; (6) parietal lobe of cerebral hemisphere; (7) parotid gland; (8) piriform lobe; (9) third ventricle; (10) articular tubercle temporal bone; (11) condylar process of the mandible; (12) medial retropharyngeal lymph node; (13) masseter muscle; (14) medial pterygoid muscle; (15) internal capsule; (16) mandible; (17) lateral ventricle; (18) corpus callosum; (19) hypophysis; (20) cavernous sinus; (21) lateral pterygoid muscle; (22) maxillary vein; (23) lingual artery; (24) maxillary artery; (25) transverse facial vein; (26) transverse facial artery; (27) facial vein; (28) lingual vein; (29) caudate nucleus; (30) diencephalon.

**Figure 12**

Figure 12: Images of the head of a clinically normal goat at the level of the middle third of the temporal fossa:

(1) frontal bone; (2) mandibular salivary gland; (3) parietal bone; (4) basisphenoid bone; (5) cerebral peduncle; (6) parietal lobe of cerebral hemisphere; (7) parotid lymph node; (8) temporal lobe of cerebral hemisphere; (9) third ventricle; (10) hippocampus; (11) parotid gland; (12) tympanic bulla; (13) temporal muscle; (14) lingual artery; (15) lingual vein; (16) mandible; (17) lateral ventricle; (18) corpus callosum; (19) maxillary vein; (20) facial vein.

**Figure 13**

Figure 13: Images of the head of a clinically normal goat at the level of the caudal contour of the mandible:

(1) frontal bone; (2) mandibular salivary gland (3); parietal bone; (4) occipital bone; (5) occipital lobe of cerebral hemisphere; (6) temporal lobe of cerebral hemisphere; (7) temporal bone; (8) longus capitis; (9) mesencephalic tectum; (10) mesencephalic aqueduct; (11) parotid salivary gland; (12) medial retropharyngeal lymph node; (13) temporal muscle; (14) tympanic bulla; (15) linguofacial vein; (16) external carotid artery; (17) mesencephalon; (18) external ear canal; (19) maxillary vein; (20) lingual artery.

**Figure 14**

Figure 14: Images of the head of a clinically normal goat at the level of the thyroid cartilage of the larynx:

(1) cerebellar hemisphere; (2) mandibular salivary gland; (3) parietal bone; (4) occipital bone; (5) occipital lobe of cerebral hemisphere; (6) longitudinal cerebral fissure; (7) temporal bone; (8) thyroid cartilage; (9) fourth ventricle; (10) arytenoid cartilage; (11) parotid salivary gland; (12) medial retropharyngeal lymph node; (13) temporal muscle; (14) lingual artery; (15) linguofacial vein; (16) external carotid artery; (17) medulla oblongata; (18) longus capitis muscle; (19) maxillary vein; (20) tympanic bulla; (21) digastricus muscle; (22) transverse cerebral fissure.

**Figure 15**

Figure 15: Images of the head of a clinically normal goat at the level of the rostral contour of the paracondylar process of the occipital bone:

(1) cerebellar hemisphere; (2) mandibular salivary gland; (3) paracondylar process; (4) occipital bone; (5) cerebellar vermis; (6) cerebellar white matter; (7) esophagus; (8) thyroid cartilage; (9) longus capitis muscle; (10) arytenoid cartilage; (11) parotid salivary gland; (12) medulla oblongata; (13) temporal muscle; (14) digastricus muscle; (15) linguofacial vein; (16) external carotid artery; (17) maxillary vein.

**Figure 16**

Figure 16: Images of the head of a clinically normal goat at the level of the occipital condyles: (1) spinal cord; (2) mandibular salivary gland; (3) occipital condyle (4) occipital bone; (5) longus capitis muscle; (6) rectus capitis ventralis muscle; (7) common carotid artery; (8) cricoid cartilage; (9) caudal horn of the thyroid cartilage; (10) esophagus; (11) paracondylar process; (12) temporal muscle; (13) rectus capitis lateralis muscle; (14) linguofacial vein; (15) maxillary vein.

**Figure 17**

Midsagittal images of the head of a clinically normal goat. The top left photograph represents the anatomic section with the corresponding pre-contrast CT image in a bone window (top right), and pre-contrast (bottom left) and post-contrast (bottom right) CT images in a soft tissue window. Rostral is to the left and caudal is to the right.

(1) nasal bone; (2) frontal sinus; (3) frontal bone; (4) parietal bone; (5) occipital bone; (6) basisphenoid bone; (7) presphenoid bone; (8) palatine bone; (9) maxilla; (10) incisive bone; (11) ventral nasal concha; (12) dorsal nasal concha; (13) middle nasal concha; (14) mandible; (15) dorsal nasal meatus; (16) middle nasal meatus; (17) ventral nasal meatus; (18) basihyoid; (19) epiglottis; (20) soft palate; (21) thyroid cartilage; (22) cricoid cartilage; (23) arytenoid cartilage; (24) esophagus; (25) optic nerve; (26) hypophysis; (27) spinal cord; (28) medulla oblongata; (29) pons; (30) corpus callosum; (31) fornix; (32) cerebral hemisphere; (33) lateral

ventricle (septum pellucidum); (34) mesencephalon; (35) cerebellum; (36) tongue; (37) trachea; (38) ethmoid conchae.

**Figure 18**

Three-dimensional surface rendering reconstructions of the head of a goat. By this technique the skin surface as well as the air-soft tissue inter-phase of the nasal cavity, nasal conchae, paranasal sinuses, oro- and naso-pharynx can be identified. The frontal sinus and the maxillary sinus including its extension into the palatine and lacrimal sinuses are highlighted in blue and pink respectively. The teeth are also highlighted in color. Note the location, shape and extension of the paranasal sinuses.

**Figure 19**

Transverse CT image of a clinically normal goat at the level of the small opening between the maxillary sinus and the nasal cavity (arrow). Left is to the left and right is to the right.

**Figure 20**

Transverse CT images of a clinically normal goat at the level of the pituitary fossa. In the pre-contrast study (A) the contours of the pituitary gland cannot be identified due to the minimal difference in density between the gland and the surrounding rete mirabile. In the post-contrast study (B) a different pattern of enhancement between the pituitary gland (short arrow) and the surrounding cavernous sinus (long arrow) greatly facilitates the delineation of the contours of the gland. Left is to the left and right is to the right.

**Figure 21**

Image A represents a mid-sagittal section of the head through the pituitary gland (arrows). The white arrowhead points at the stalk of the pituitary extending in a caudoventral direction into the adenohypophysis. The black arrow indicates the adenohypophysis while the white arrow marks the neurohypophysis. Transverse (B) and reconstructed sagittal (C) CT image at the level of the caudal third of the pituitary gland obtained 30 seconds after start of the contrast medium injection. Note the enhancement of the neurohypophysis located at the dorsocaudal aspect of the gland (white arrowhead). Transverse (D) and reconstructed sagittal (E) CT image at the level of the rostral third of the pituitary gland obtained 40 seconds after the start of the contrast medium injection. Note the enhancement of the rostrodorsal aspect of the pituitary gland representing the portal vessels in the pituitary stalk (white arrowhead).

## **Acknowledgements**

I am most grateful for getting the chance to do a doctoral thesis under the supervision of Prof. Dr. U. Braun and PD Dr. S. Ohlerth.

Many thanks go to Prof. Dr. H. Augsburger and U. Müller for the support with the anatomic sections, the photographic work and the image labelling.

Such a work would have not been possible without the strong support of co-workers. Therefore, I owe a thousand thanks to Dr. M. Becker-Birck, Dr. M. Irmer, Dr. K. Steininger, Dr. D. Jaquat, Dr. A. Tschuor, Dr. R. Jud and the radiology technicians.

I also thank Prof. Dr. H. Lutz for the blood examinations and Prof. Dr. P. Deplazes for the parasitological examinations.

Many thanks go to my family and to everybody not mentioned in particular, for adding to the success of this work, for their mental support and for their friendship.

## Curriculum vitae

Name	Makara, Mariano Andrés
Date of birth	June 27, 1975
Place of birth	Buenos Aires, Argentina
Nationality	Argentina
1988 – 1992	Primary and High school (Quilmes High School), Buenos Aires, Argentina (a bilingual English school) Degree: „Bachiller Bilingüe con Orientación en Ciencias y Letras“ Additional qualifications: „International General Certificate of Secondary Education (Cambridge University)“
1993 – 1999	Universidad Nacional de La Plata (National University of La Plata) Buenos Aires, Argentina Degree: Medico Veterinario
1999 – 2002	Assistant Professor, Physiology Department, National University of La Plata, Buenos Aires, Argentina
1999 – 2004	Assistant Position in small animals and diagnostic imaging, private practice of Dr. Olga Den Toom, Olivos, Argentina
2005 – 2007	Internship in diagnostic imaging (Mentor Prof. Dr. J. Morgan), Ross University, Dominica, West Indies, USA
2007 – 2010	Doctoral Thesis, Section of Diagnostic Imaging and Department of Farm Animals, Vetsuisse Faculty, University of Zurich, Switzerland
2007 – dato	Resident ECVDI, Vetsuisse Faculty, University of Zurich, Switzerland
